BACKGROUND

This product relates to the improvements in devices to divert/collect water from roofs of houses, buildings etc.

As well publicised in Australia water is a scarce commodity and in its worst drought in history. Combined with an ever growing population, water reserves are at very low levels.

Restrictions in the way we use mains water are currently very tight. Rainwater and greywater harvested on our own properties may well be the only way we will be able to water our gardens.

Water from rainfall that falls onto roofs of houses currently goes into the stormwater system. Before development this water would have soaked into the ground.

Having access to this rainwater and to be able to controllably divert it to the garden or for collection in any form would have tremendous advantages for the garden.

Diverting rainwater also gives a heavy concentrate of water to the ground that the rain itself would not do. Natural rainwater is also much better then mains water.
